

I believe that Tufte would like my chart because it is minimalistic. It only shows the unaltered data and has consistent bounds. I achieved this by removing the pre-1943 data points because it would skew the consistency of the X axis. I also believe that it shows interesting trends such as why did the total amount of southeast sterilizations go up after 1947, and why did the amount of sterilizations in the west decrease around that time. One thing that I could probably improve is the labeling of the different lines, by labelling them directly on the graph. Also Tufte may have preferred lines that were grayscale.
